Among the types of endomycorrhizal fungi, arbuscular mycorrhizal (AM) fungi are the most prevalent in soils. Their name is derived from structures they form within the plant root cell: arbuscules*. *Arbuscules are finely-branched structures that form within a cell and serve as a major metabolic exchange site between the plant and the fungus.

Mycorrhizae play important roles in plant nutrition, soil biology and soil chemistry. In a mycorrhizal association, the fungus colonizes the host plant's root tissues, either intracellularly as in arbuscular mycorrhizal fungi (AMF or AM), or extracellularly as in ectomycorrhizal fungi. The association is sometimes mutualistic.

Mycorrhiza - Wikipedia

Mycorrhizal fungi are beneficial fungi that are associated with plant roots via a symbiotic association whereby both the host plant and the fungus benefit. Mycorrhizae are the struc- tures formed by the symbiotic association be- tween plant roots and mycorrhizal fungi. My- corrhizae contain both plant roots and fungal tissues.

Short answer: Mycorrhizal fungi is a naturally-occurring beneficial soil organism that forms a symbiotic relationship with plant roots. For the past 460 million years an estimated 80-90% of the earth's land plants have existed with mycorrhizae naturally, in a variety of climates from dry deserts to wet rainforests.
