Carbonate reservoirs are important contributors to world oil and gas production and contain more than one-half of global discovered, recoverable hydrocarbons (Roehl and Choquette, 1985).Reef and reef-related deposits comprise a significant proportion of these reservoirs, most prominently in carbonate systems of Siluro-Devonian, Cretaceous, and Neogene age.

Carbonate reservoir descriptions are based on observations of depositional and diagenetic fabrics and pore space from coreand cuttingsamples. The descriptions are correlated with wireline logresponses and incorporated into geological facies and/or diagenetic models in order to map porosity, water saturation, and permeability.

An improved understanding of the controls on reservoir quality is key to ongoing and future exploration of the Central North Sea Triassic play. This paper presents a regional integrated study of 50 000 ft of wireline log data, 10 000 ft of core, 4431 routine core analyses measurements and 377 thin sections from 86 cored wells. Triassic Skagerrak Formation sandstones represent thin-bedded ...
